Non-Training Build Report

EnvLoop / 2 October 2026

Scope: executable infrastructure and independently checked controls. This report contains no full-study model result or measured training gain.

Date: 2 October 2026. This build assumes Tinker is unavailable. It makes no model-performance claim and does not change the full study's 4-researcher by 6-cell design.

Executable components

The controller preserves the repository layout and hash-bound runtime dependencies. It includes Chromium, Docker and Compose clients, E2B desktop clients, Harbor 0.23 with its E2B extra, application adapters, task generators, independent verifiers and English report tooling. Tinker is not installed. A source archive and its complete file-hash manifest accompany the image.

Cell	Current endpoint	Independent verification	Actual execution boundary
Excel web	tools.office_current_worker_cli_v5	Original rich SEC graph and saved workbook checks	140 original packages replayed offline; current native lifecycle pending
PowerPoint web	tools.office_current_worker_cli_v5	Saved deck text, chart and collateral checks	140 portable WDI packages built; current native lifecycle pending
Native desktop	native_desktop_factory.native_window_current_runtime	Saved Calc, Impress and Writer artifacts	Coordinate projection and repeated runtime controls verified; business edit blocked by the current LibreOffice native-state contract
Odoo Community	enterprise_fallback.odoo18.native_surface_workers_v14	Trusted SQL state, exact reset and native receipt audit	Current 20 selection and 20 pilot-final control sets independently verified
GitLab CE	gitlab_world.v066_uniform_model_workers_v14	Saved SQL plus Git trees, blobs and relationships	Two current saved control trios independently verified; complete page review pending
Magento	magento_catalog_factory.native_surface_workers_v9	Catalog SQL, search state, queue ownership and exact reset	Current baseline verified; prior reference failures retained; corrected visible-control reference is undergoing genuine native verification

Current source bindings and CLI help are checked in isolated processes inside the image. These checks construct no application worker, create no cloud guest, train no model and dispatch no inference. An application run requires its original private task allocation, owned execution resource and reviewed authority. The image alone is not a replacement application sandbox.

Preserve the difficult data

The rich Excel replay retains the original workbook bytes, source assets and trusted graph code. Its 140 packages span 33 issuer families, 140 filings and 16 graph types, including 13 final graph types. The saved replay checks 1,997 numeric facts and 9,985 formula targets. All 140 reference positives pass, all 140 unrepaired seeds fail, and all 1,260 individually isolated faults fail. Source and scenario counterfactuals are retained. These are artifact-verifier checks, not Excel-web agent outcomes.

PowerPoint uses the original current WDI plan with 20 training, 20 selection and 100 final candidates. Portable generation replaces a proprietary generation dependency without reusing old application-native qualification. Baseline, positive, near-miss, collateral-change and wrong-chart artifact controls are checked separately.

The earlier two-issuer Excel engineering pool is explicitly development-only and excluded from the current 280-package Office index. Private instructions, gold answers, task allocations, account state and credentials are not included in the public image or source archive.

What can run without Tinker

- Build the source archive and runner image; verify their complete hash manifests.
- Run offline generator, parser, verifier and browser checks, including Harbor CLI and agent imports.
- Prepare current application bindings and task metadata; inspect original-software state.
- Execute reviewed, owned reference controls and check saved state and reset.
- Generate methods and evidence reports from completed checks.

Training, checkpoint selection and a trained-versus-base matched comparison remain blocked by the unavailable training provider. The full study still requires 600 independently admitted final identities, 24 completed researcher chains and 3,000 reconciled matched model outcomes. This build contributes zero official final identities, chains or outcomes.

External requirements

Original Office web needs the existing signed-in browser and permission to upload owned files. Chrome's ChatGPT extension currently refuses local-file upload until "Allow access to file URLs" is enabled. A native file-picker fallback also requires the Mac to be unlocked. The actual system is currently locked. No second Office account is required for this lightweight owned-folder path.

Linux application resources and E2B credentials are supplied at runtime. Docker daemon access is supplied explicitly for owned container operations. These resources are not embedded in the controller image. Public GHCR publication uses the repository's CI token with package-write permission; it is separate from a successful local image build.

Reproduce the build

See README.md for staging, build and network-isolated verification commands. Keep the original output and supervision receipts when an actual control fails. An infrastructure failure receives no invented score and is not silently replayed. Additive runtime repairs require fresh source witnesses; older native controls are not automatically promoted into a changed epoch.

Validation record

The current controller profile passed 3,232 tests with 64 conditional skips. The seven Desktop SDK tests passed separately in a compatible E2B Desktop 2.2 / Pillow 11.3 interpreter. A fresh network-blocked dispatch-gate suite passed 44 fake-provider tests without replacing its historical September receipt. The latest visible-toolbar reference regression rejects ambiguous visible controls and accepts the single visible original control while excluding its hidden sticky clone. These tests and source checks contribute no model outcome or native task admission.
